“ What the Internet did for communications,
blockchain will do for **trusted transactions** ”

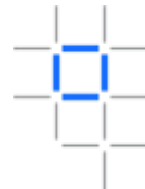

- Ginni Rometty (THINK Forum 2017)

What is Blockchain?

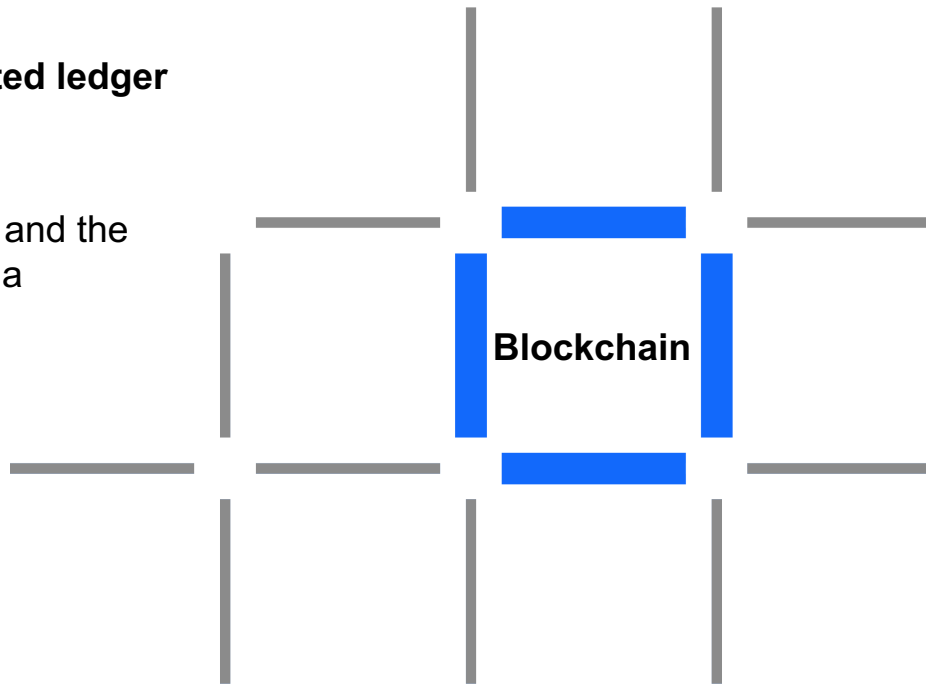

What is blockchain?

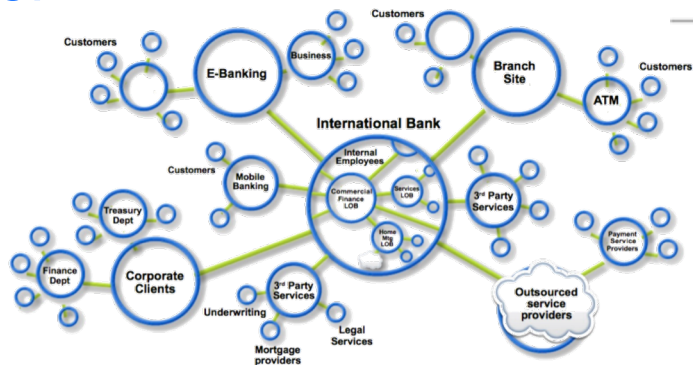

Blockchain is a **shared, immutable and distributed ledger** for recording the history of transactions.

A **business blockchain**, such as IBM Blockchain and the Linux Foundation's Hyperledger Project, provides a **permissioned network** with known identities.

Business networks and assets transfer

- An **asset** is anything that can be owned or controlled to produce value, for example: goods and services
- Assets can be
 - **Tangible**, e.g. shipping containers, food products, spare parts, land,
 - **Intangible**, e.g. intellectual properties (patents, trademarks), financial (bonds, invoices), digital goods (music, e-books)
- Assets are transferred through **business networks** comprised of **participants** (for example, customers, suppliers, service providers, banks) across **regulatory and geographical boundaries**
- **Transactions** describe the exchange of assets between participants

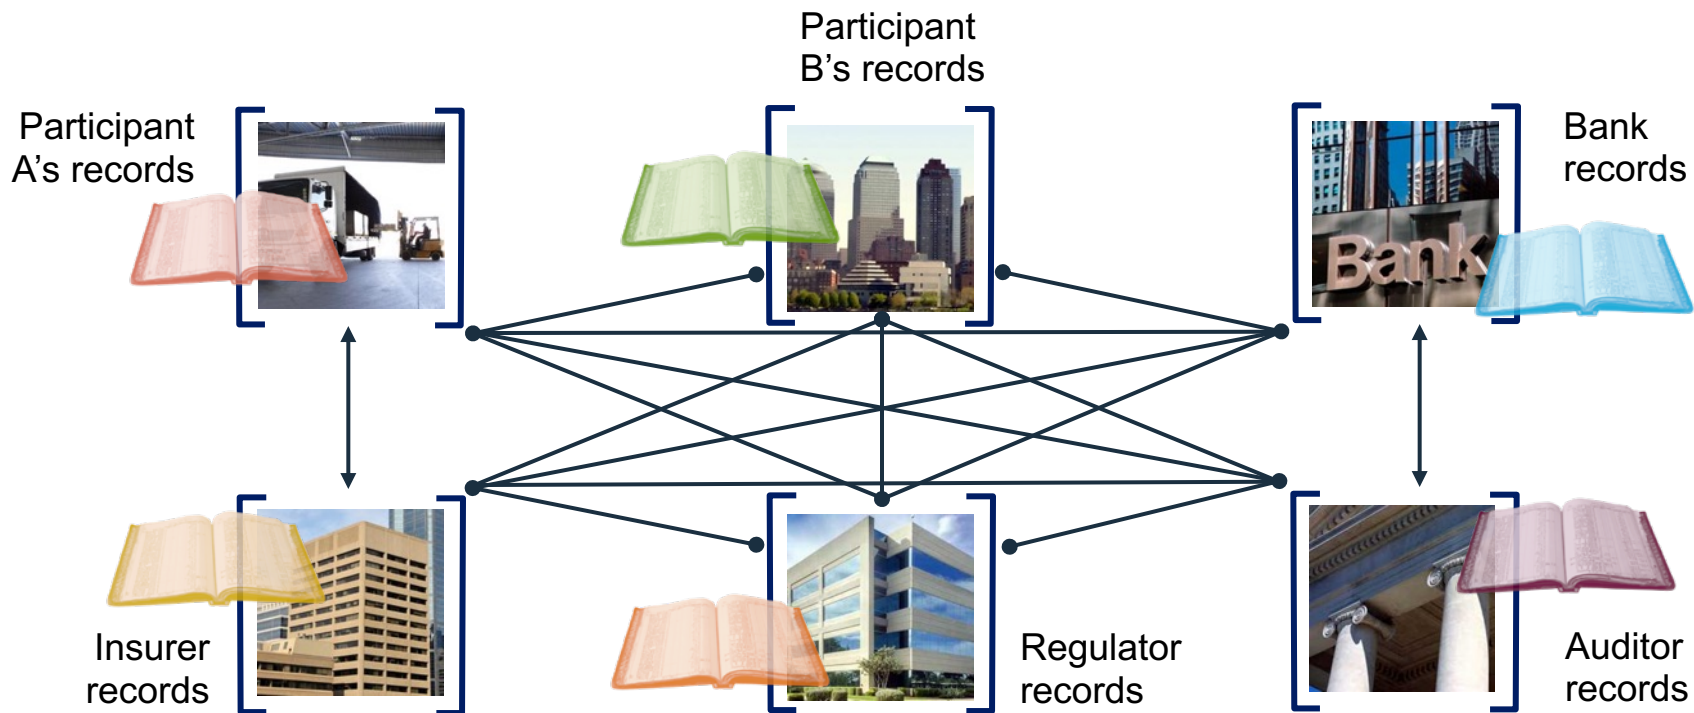

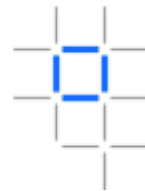

Each participant records transactions in **ledgers**. The **ledger** is a log of transactions, and the **key system of record** for asset exchange for a business.

Contracts are a set of business terms that should be met by participants before a transaction is completed.

A **market** is the flow of assets across business networks

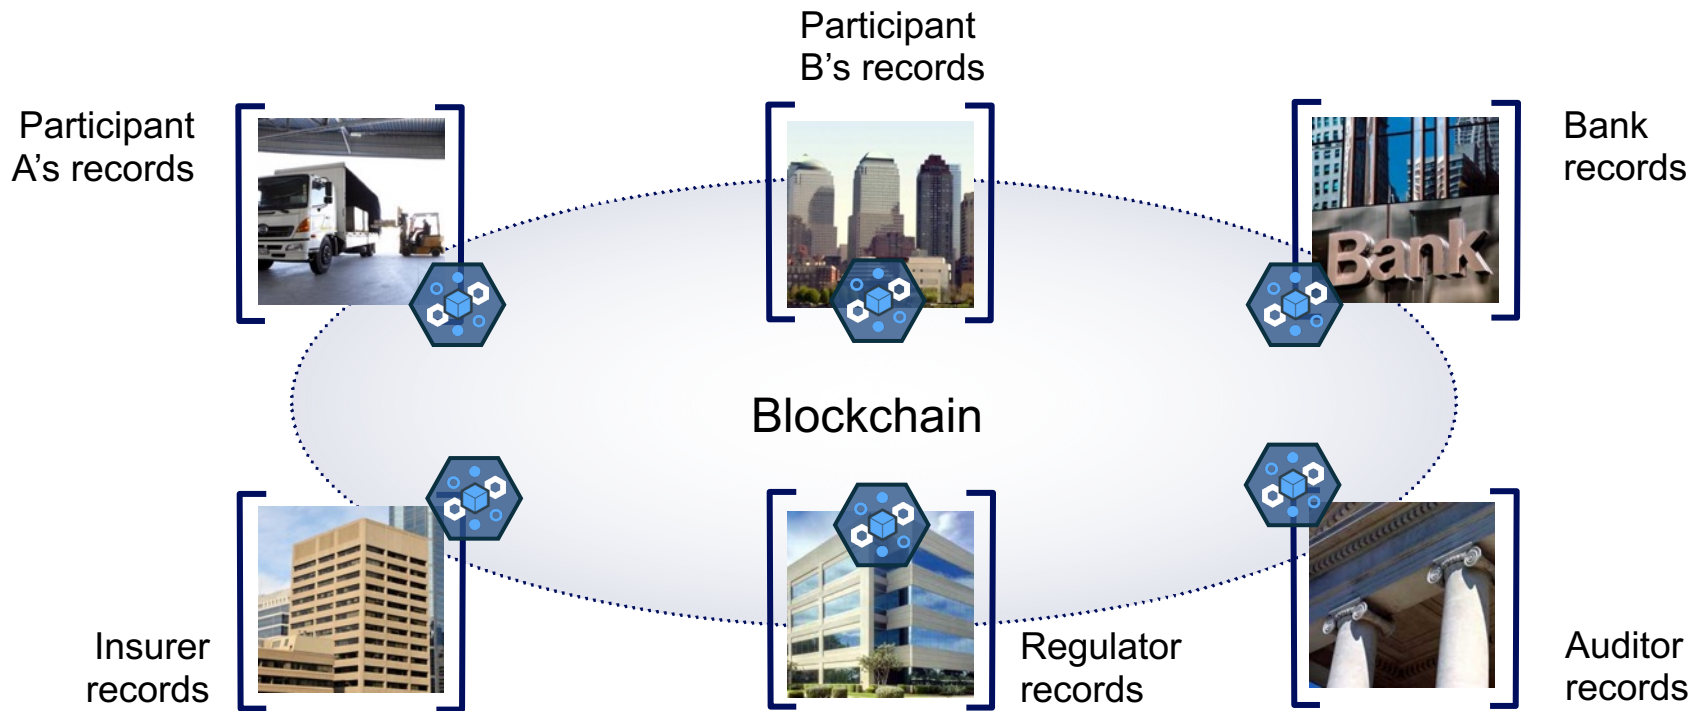

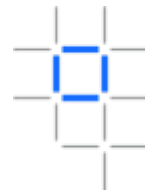

- Public (market, car auction)
- Private (supply chain financing, bonds)

Problem: transferring the ownership of a vehicle

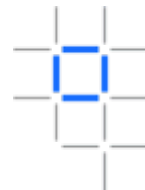

... inefficient, expensive, vulnerable

A shared, replicated, permissioned ledger ...

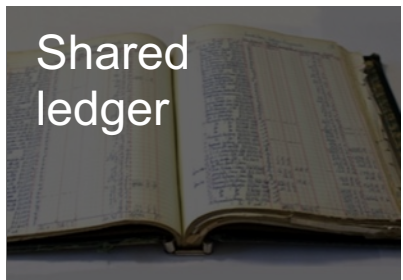

... with consensus, provenance, immutability, and finality

Blockchain for business requirements

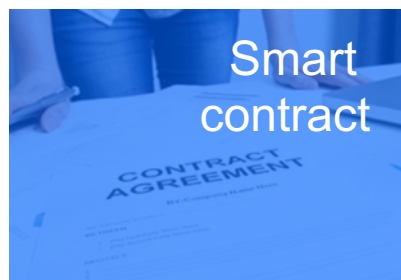

Append-only
distributed system of
records shared
across business
networks

Shared
ledger

Smart
contract

Business
terms
executed with
transactions

Transactions
are secure with
appropriate
visibility

Privacy

Accountability

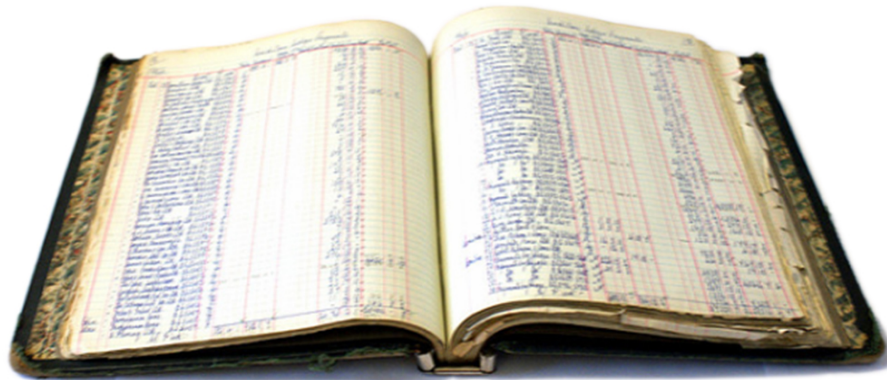

Transactions are
provably endorsed
by relevant
participants

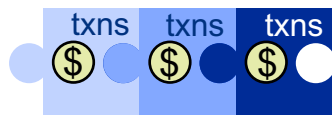

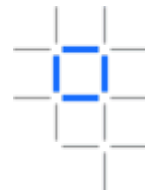

Shared ledger

- Shared between participants
- Participants have own copy through replication
- Permissioned, so participants see only appropriate transactions
- THE shared system of record
- Immutable due to an append-only data structure

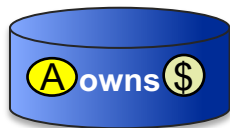

Records all transactions across business networks

Shared ledger: Components

Blockchain

World state

- **Blockchain**

The chain provides an immutable, transparent record of transactions

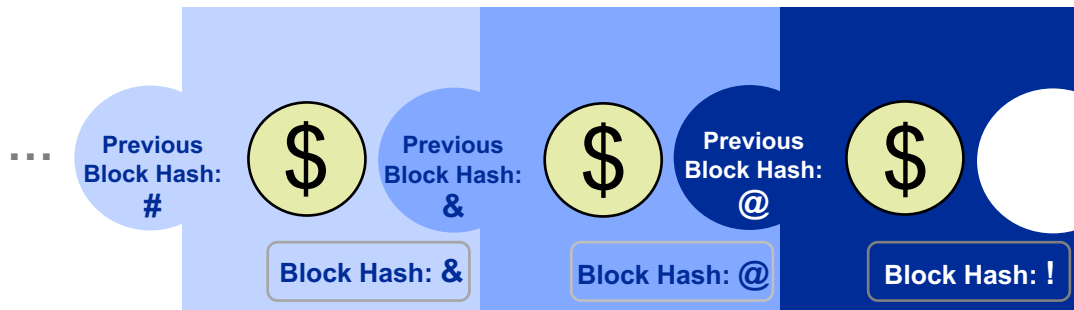

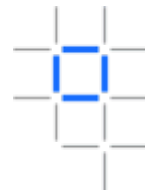

- A **linked list of blocks**
- Each block describes a **set of transactions**
- **Immutable** – blocks cannot be tampered with

- **World State**

The world state stores the current state of assets

- An ordinary **database** (e.g. key/value store)
- Stores the **combined outputs of all transactions**
- Not usually immutable

Shared ledger: Blockchain immutability

- A blockchain is made up of a series of blocks, with new blocks always added to the end
- Each block includes the result of a hash function of the previous block
- Immutability: If someone tries to tamper with a transaction's outcome, the block's hash is updated, violating the integrity of the blockchain. Hence the change is rejected.

Smart contract

- Verifiable, signed
- Business rules, written in programming languages, supported by the blockchain technology
- Examples:
 - Defines contractual conditions under which a bond transfer occurs
 - Defines rules on which a vehicle can be transferred to a new owner

Business rules associated with the transaction

Privacy

- Participants require:
 - Appropriate **privacy** and **confidentiality** between subsets of participants
 - Identity not linked to a transaction
- Transactions need to be authenticated
- Cryptography is central to these processes

The ledger is shared, but participants require privacy and confidentiality

Accountability

- Participants endorse transactions
 - **Consensus**: Participants agree that a transaction is valid
 - Business network decides who will endorse transactions
 - Endorsed transactions are added to the ledger with appropriate confidentiality

The ledger is a provable source of information

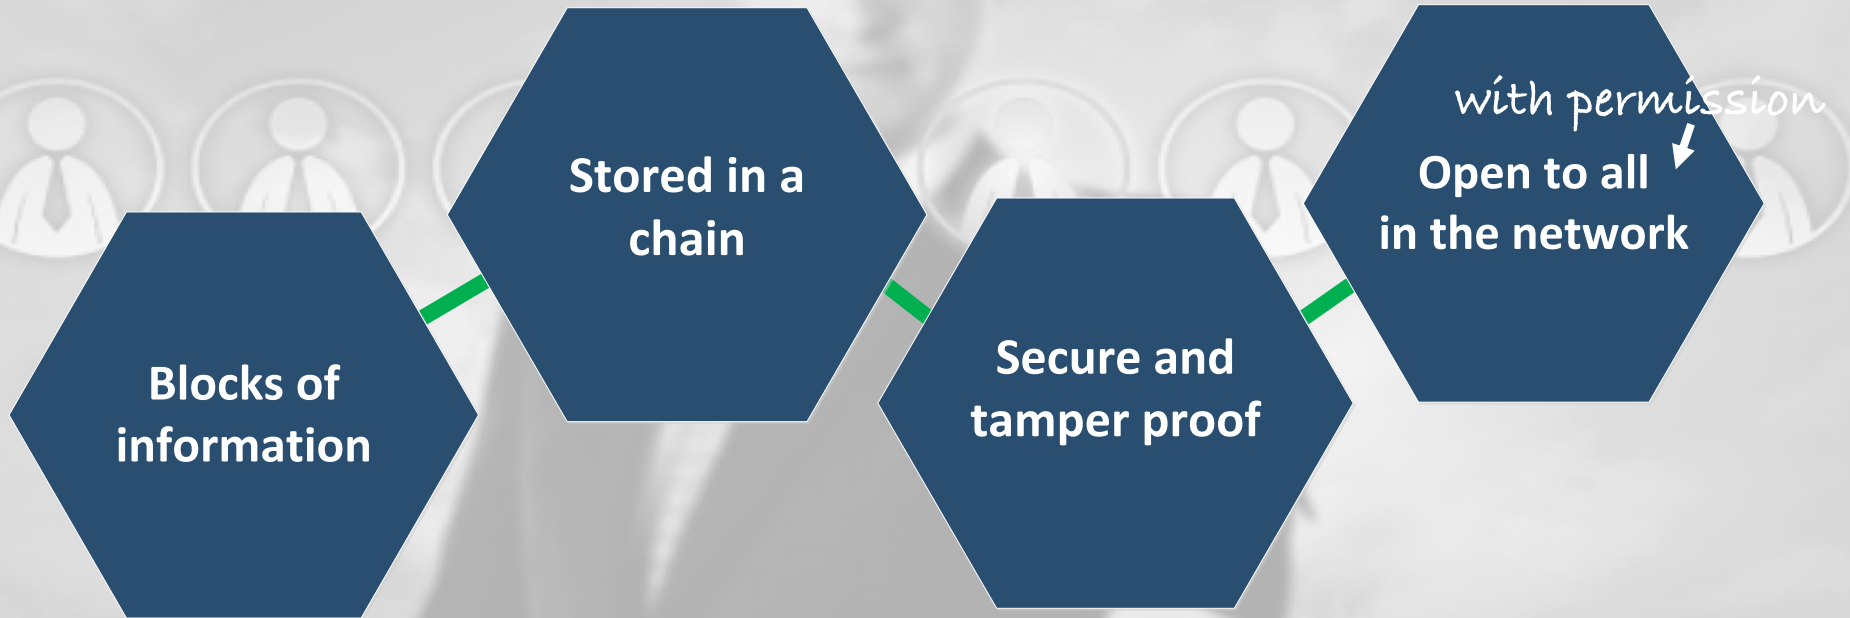

Accountability (continued)

- Assets have a verifiable audit trail
 - **Provenance**: Participants know where the asset came from and how its ownership has changed over time
 - **Immutability**: No participant can tamper with a transaction once it is agreed upon
 - Transactions can not be modified, inserted or deleted
 - **Finality**: Only one place to determine the ownership of an asset or completion of a transaction (the shared ledger).

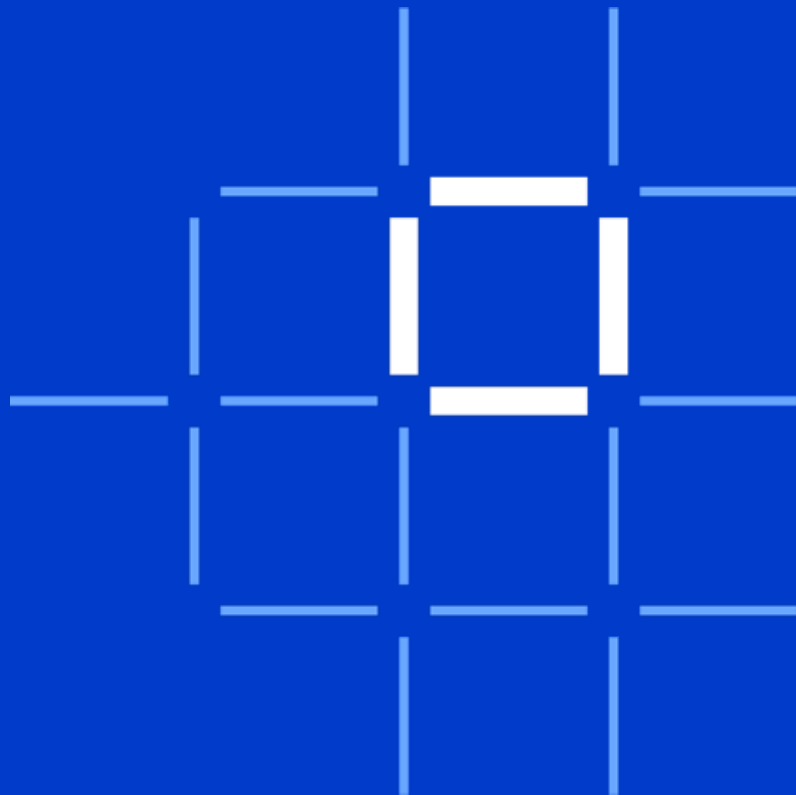

The ledger is a provable source of information

The basic premise of Blockchain is simple...

Blockchain for Healthcare

Trust Challenges are Inherent in Complex Ecosystem ...

Each day, leaders, advocates and influencers in health strive to progress towards a healthier future for individuals, families, communities, and work places

Outcome-based Care

- Fee-for-value instead of Fee-for-Services

Interoperability and Data Ownership

- Data silos and data complexity
- Lack of clear data ownership
- Data hoarding for competitive advantages

Regulation and Compliance

- Complex regulatory landscape with increasing regulation for patient access, consent and control of their data

Privacy & Security

- Frequent cyber attacks and large-scale data breaches
- Increasing patient concerns about data privacy

Fraud, Abuse & Complexity

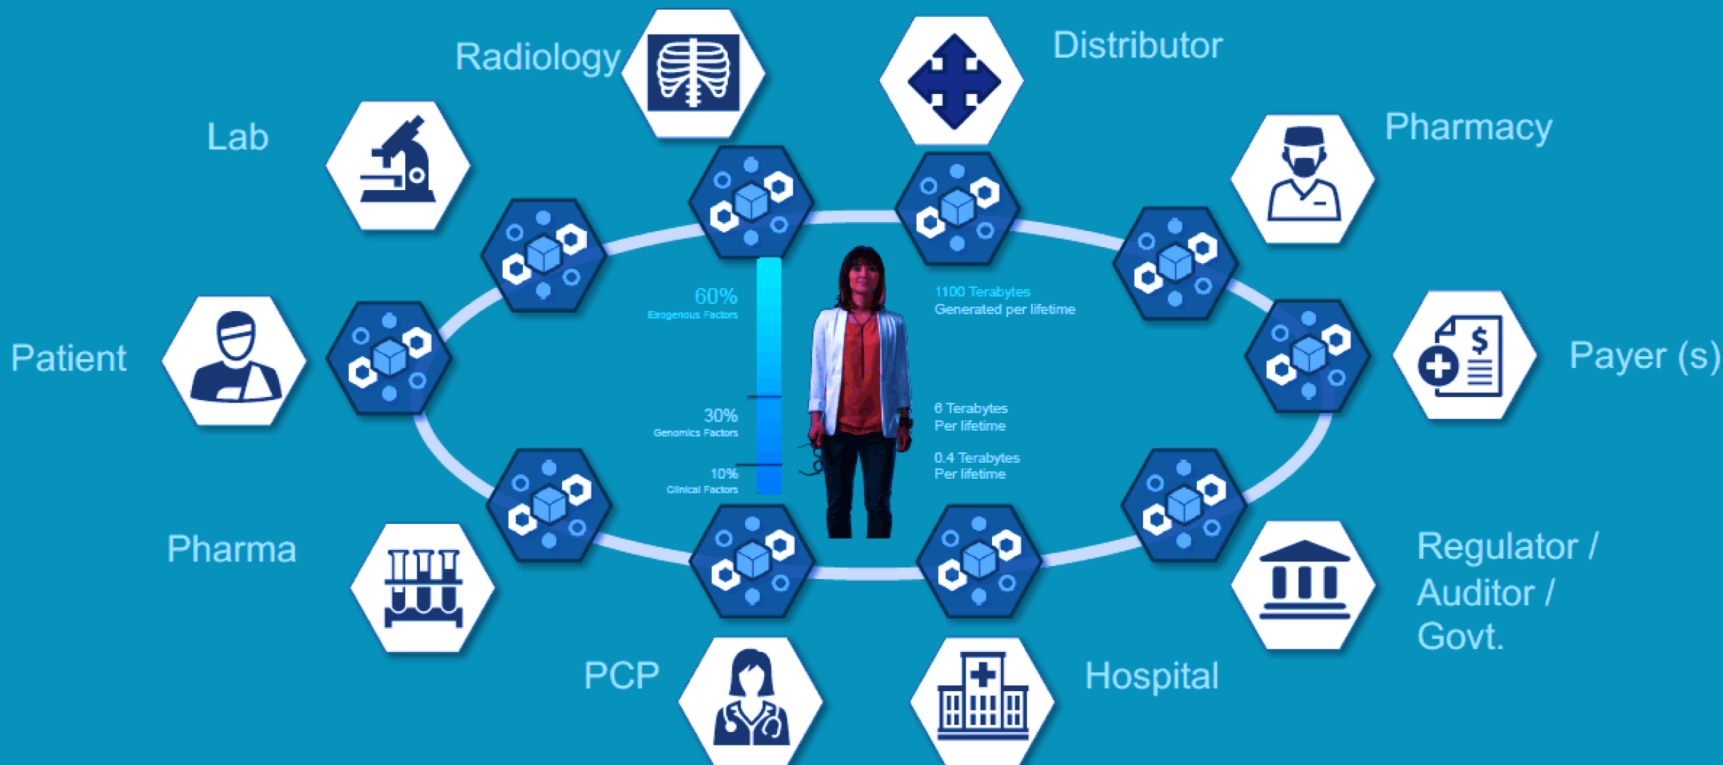

- False claims, corruption and abuse
- Limited traceability and accountability

Healthcare and Blockchain

Secure, data exchange and sharing across the health eco-system

Compliance, integrity, provenance

Blockchain use cases in Healthcare and Life Sciences

Patient Consent and Health Data Exchange

- Patient control of his/her health data
- Secure medical data exchange including EMR, genomics, image, exogenous
- Blockchain ensures consent, compliance, auditability, provenance, governance

Outcome-based Care Platform

- Contract between Payer and Provider or Pharma for outcome based payment in BC
- Contract, data and computation of outcomes in SmartContracts
- Outcomes accessible by authorized participants
- Blockchain provides trust among parties on outcomes with provenance and auditability

Clinical Trial Management

- Clinical trials data exchange automation with auditability, provenance, traceability
- Use blockchain for regulatory processes, oversight, fraud detection
- Traceability of protocol design elements to data collection

Blockchain use cases in Healthcare and Life Sciences

Provider Credentialing/ Directories

- Provider information is often out-of-date, incomplete, and inaccurate. It creates a burden on payers, consumers and also providers. Increases fraud
- Validation and updating of data can be tracked much easier. Benefits plans and patients. Lessens provider burden

Payment and Medical Claims Processing

- Reimbursement rules unclear and not transparent
- Smart Contract between Provider / Payer / Patient
- Rethinking medical claims processing and replacing healthcare clearing house
- Reduce process time and friction, including compliance with contract terms, less audits

Prior Authorization

- Delays care. Creates confusion with providers and patients. Increases costs of care.
- Smart contracts allow rules to be codified and automated

Eligibility-eg. Medicaid

- Large amount of people coming on and off Medicaid creates admin expenses and fraud opportunities
- Decreased expenses and fraud. Better service

Blockchain use cases in Healthcare and Life Sciences

Drug Supply Chain Provenance and traceability

- Motivated by patient safety, counterfeit fraud, drug traceability, brand protection
- FDA and EMA regulations, e.g. FDA DQSA

Gross-to-Net Revenue (Rebates) Management

- Revenue leakage costs Life Sciences companies billions in lost revenue
- Fewer disputes, faster settlement, improved accrual forecast accuracy, fewer revenue dollars lost to leakage

Thank you
